

The `arraycols` package*

Antoine Missier
`antoine.missier@ac-toulouse.fr`

September 13, 2023

1 Introduction

This package introduces new predefined column types for tables, in addition to the `array` package by Frank Mittelbach and David Carlisle [1]. It also includes a command for wide horizontal rule drawing. Below is a summary of the column types and macro defined by `arraycols`, which will be detailed in the following section.

Column definitions	
<code>L</code>	Left adjusted column (applicable in LR mode for <code>array</code> environments or math mode for <code>tabular</code> environment)
<code>C</code>	Centered-adjusted column (similar to <code>L</code> but centered)
<code>R</code>	Right-adjusted column (similar to <code>L</code> but right-adjusted)
<code>t{width}</code>	Text column of fixed $\langle width \rangle$ (LR mode), similar to <code>p</code> , but with horizontal and vertical centering
<code>x</code>	Centered column in math mode with adjusted height to avoid touching the horizontal rules
<code>y</code>	Left-aligned column in math mode with adjusted height
<code>z{width}</code>	Centered column in math mode, similar to <code>x</code> , with adjusted height, but with fixed $\langle width \rangle$
<code>T</code>	Centered text column with adjusted width for <code>tabularx</code> environments (calculated like <code>X</code> column)
<code>Z</code>	Centered column for <code>tabularx</code> , similar to <code>T</code> , but in math mode with adjusted height, like <code>x</code> and <code>z</code>
<code>I</code>	Thick vertical rule (1 pt)
<code>V{thickness}</code>	Vertical rule with variable $\langle thickness \rangle$
Horizontal rules	
<code>\whline</code>	Wide horizontal rule (1 pt)

Note that if a column type has been previously defined by another package, using `arraycols` will overwrite it and display a warning message.

*This document corresponds to `arraycols` v1.4, dated 2023/09/13. Thanks to François Bastouil for assistance with the English translation.

In addition to loading the `array` package, `arraycols` also requires `cellspace` [2], which is necessary for the `x`, `y`, `z` and `Z` column types. Moreover it relies on `tabularx` [3] for `T` and `Z` column types and loads `makecell` [4] for creation of multilined tabular cells. It's worth mentioning that the `tablestyles` package [6] also defines `L`, `C`, `R` and `Z` column types, but differently. Nevertheless, `tablestyles` is incompatible with `makecell` and consequently with `arraycols` as well.

With its minimal code, `arraycols` makes no claim to develop new macros. Its purpose is to combine and configure functionalities derived from other packages.

2 Usage

- L Referring to an example from the `array` package documentation, the `L`, `C` and `C`
- R `R` columns types, enable the reversal of the mathematical mode. This allows
- R to achieve centered, left-aligned or right-aligned LR-mode in an `array` environment or an equivalent math-mode in a `tabular` environment. For instance, using the declaration `\begin{tabular}{|l|C|r|}` sets the second column in centered mathematical mode. Similarly, using the declaration `\begin{array}{|L|c|c|}` sets the first column in text mode, left-aligned¹.

`t{width}` The newly introduced column type definition `t{width}` horizontally and vertically centers paragraphs within the column, with a specified `width`. In contrast, the traditional `p{width}` (in standard L^AT_EX) and `m{width}` (from the `array` package) column types, justifies paragraphs, while text in `t{width}` is centered.

- x In order to guarantee adequate row heights, especially for displaymath mode
- y formulas, the package includes the column types `x` (centered) and `y` (left aligned). These column types activate the mathematical mode and allow automatic adjustment of row heights to prevent any overlap with horizontal rules in cases where the content is too tall, thanks to a functionality of the `cellspace` package by Joselin Noirel [2]. While `cellspace` is initially designed for `tabular` environments, the new `x` and `y` column types are applicable in both `tabular` and `array` environments. Examine the following examples created using `\begin{array}{|c|}` and `\begin{array}{|x|}`.

bad	good
$\lim_{\substack{x \rightarrow 1 \\ x > 1}} \ln \left(\frac{x^2}{x-1} \right)$	$\lim_{\substack{x \rightarrow 1 \\ x > 1}} \ln \left(\frac{x^2}{x-1} \right)$
$\frac{a}{\frac{b}{}}$	$\frac{a}{\frac{b}{}}$
$\int_1^X \frac{1}{t} dt$	$\int_1^X \frac{1}{t} dt$

¹The declarations `L`, `C`, `R` do not work in a `tabularx` environment. Additionally, the `tabulary` package by David Carlisle [5] already defines the `L`, `C`, `R` (and `J`) column types for specific alignments in tables of the same type as `tabularx`. However, there is no incompatibility with `arraycols` because these column definitions apply exclusively within `tabulary` environments.

The `cellspace` package is loaded with the `math` option² to efficiently manage row heights, including in matrices. Another option of `cellspace`, `column=Q` (with `S` being the default in `cellspace`)³, was necessary to prevent any compatibility issues with the `siunitx` package (also loaded by `pstricks-add`). The `Q` declaration serves as a “modifier” that, when placed before a column type declaration, permits the adjustment of cell height, for instance “`Qc`” for a vertical adjustment within a centered column type.

Notice that another package, `booktabs` [7], also offers excellent row height adjustment. However, regrettably, it doesn’t handle the height of vertical separators “|”. In order to achieve a similar vertical adjustment as `booktabs`, we set the `cellspace` parameters as follows:

```
\setlength{\cellspacetoplimit}{3pt},
\setlength{\cellspacebottomlimit}{2pt}.
```

Additionally, it’s worth mentioning the `tbls` package by Donald Arneseau [8] that makes a good adjustment of row heights as well, but it is incompatible with the `array` and `numprint` packages.

Finally, manual adjustments can also be achieved using the `\vstrut` command from the `spacingtricks` package [10], or by utilizing `\gape` and `\Gape` from the `makecell` package [4], as well as employing `\bigstrut` from the `bigstrut` package [9].

`z{<width>}` The `z{<width>}` column type activates the mathematical mode and allows to define the column width, similar to `t{<width>}`. It also adjusts the row height, akin to the `x` column type. The content consist of a single line. When it becomes too wide, it may protrude to the right.

`T` The `tabularx` package by David Carlisle [3] introduces the `X` column definition, which calculates its width in relation to the required width for the entire table. It aligns text to the left similar to `p{<width>}`. For instance, using `\begin{tabularx}{8cm}{|c|X|X|}` adjusts the width of the `X` columns to achieve a total width of 8 cm. To complement this, we offer the `T` declaration, which performs a similar function but centers the content horizontally. Additionally the `Z` declaration activates mathematical mode and adjusts line heights, comparable to `x` or `z`. Here’s an example with `\begin{tabularx}{\linewidth}{|T|y|x|Z|T|}`.

A good job	$\lim_{\substack{x \rightarrow 1 \\ x > 1}} \ln \left(\frac{x^2}{x-1} \right)$	$\frac{a}{b}$	$\frac{a}{b} + \int_1^X \frac{1}{t} dt$	a multi-line piece of text
------------	---	---------------	---	-------------------------------

Observe that cells 3 and 4 are not vertically centered to preserve the precise alignment of fraction bars within mathematical formulas across cells. For achieving accurate vertical positioning within the last cell, we have used the powerful `\makecell[<pos>]{<content>}` command from the `makecell` package by Olga Lapko [4]: `\makecell{a multi-line \ \ piece of text}`.

²The `math` option loads the `amsmath` package. As mentioned in the `cellspace` package documentation: “the `amsmath` package can be loaded beforehand with other packages (such as `empheq` or `mathtools`), were an incompatibility to arise from one’s loading it later”.

³The letter `Q` is a substitute for the default column modifier `S` of the `cellspace` package.

`I` The column definition `I` is mentioned in The L^AT_EX Companion [11] and allows
`V{thickness}` for drawing a thicker *vertical* line (1 pt thick) compared to the one achieved with
the standard declaration “`|`”. For selecting the line thickness, we additionally
provide the column definition `V{thickness}`⁴.

`\whline` Similarly, the `\whline` command, suggested in The L^AT_EX Companion, en-
ables the drawing of a thicker *horizontal* line (1 pt thick) compared to the line
obtained with `\hline`. Moreover, the `makecell` package provides the command
`\Xhline{thickness}` enabling the choice of horizontal rule thickness.

The introductory table has been typeset with a column declaration `I` serving as
a separator between the two text columns. Horizontal rules at the beginning and
end of the table are accomplished using `\whline`, while a `\Xhline{0.8pt}` rule
is employed after the legend rows. The formatting of header rows is achieved
using the `\thead` command from the `makecell` package. By default, `arraycols`
sets: `\renewcommand\theadfont{\footnotesize\sffamily}` (in `makecell` it is
`\footnotesize` only, without `\sffamily`). Lastly, following a recommendation
of the `array` package [1], an additional 1 pt has been added to the standard height
of each row within this table. This adjustment is implemented with the command
`\setlength{\extrarowheight}{1pt}`⁵.

3 Implementation

```

1 \RequirePackage{array}
2 \RequirePackage[math,column=Q]{cellspace}
3 \RequirePackage{tabularx} % must be loaded after cellspace
4 \RequirePackage{makecell}
5
6 \newcolumntype{C}{>{$}c<{$}}
7 \newcolumntype{L}{>{$}l<{$}}
8 \newcolumntype{R}{>{$}r<{$}}
9 \newcolumntype{t}[1]{>{\centering\arraybackslash}m{#1}}

```

The `cellspace` package provides the `S` modifier (we used `Q` instead), which, when
placed before a column declaration, allows for the adjustment of cell content
height to prevent any overlap with horizontal rules. The spacing between the
content and the rules is governed by the parameters `\cellspacetoplimit` and
`\cellspacebottomlimit`.

```

10 \newcolumntype{x}{>{$}Qc<{$}}
11 \newcolumntype{y}{>{$}Ql<{$}}
12 \setlength{\cellspacetoplimit}{3pt}
13 \setlength{\cellspacebottomlimit}{2pt}
14 \newcolumntype{z}[1]{>{$}Q{>{\centering\arraybackslash}p{#1}}<{$}}

```

⁴The definition of `V` would have been simplified by utilizing an optional argument for `I`, but
unfortunately, this approach doesn’t function.

⁵As stated in the `array` package documentation: “This is important for tables with horizontal
lines because those lines normally touch the capital letters”.

For the `z` column type, we employed the `p` declaration instead of `m` (which should automatically center content). This choice ensures proper alignment of mathematical expressions within cells of the same row. The same result can be achieved with the following definition: `\newcolumnntype{z}[1]{>{\$}Q{W{c}{#1}}<{\$}}` with `W{c}` defined in the `array` package.

```
15 \newcolumnntype{T}{>{\centering\arraybackslash}X}
16 \newcolumnntype{Z}{>{\$}QT<{\$}}
```

Like `X`, the `T` columns are not vertically centered. Although it's possible to achieve this by using the command `\renewcommand{\tabularxcolumn}[1]{m{#1}}` (with `m` instead of default value `p`), unfortunately, this approach has a global effect on all column declarations based on `X`, including `T` and `Z`. As a result, it could disrupt the alignment of mathematical expressions within cells of the same row.

```
17 \newcolumnntype{I}{!{\vrule width 1pt}}
18 \newcolumnntype{V}[1]{!{\vrule width #1}}
19 \newlength\savedwidth
20 \newcommand{\whline}{%
21   \noalign{\global\savedwidth\arrayrulewidth\global\arrayrulewidth 1pt}
22   \hline
23   \noalign{\global\arrayrulewidth\savedwidth}
24 }
25 \renewcommand\theadfont{\footnotesize\sffamily}
```
